

The slide features a minimalist design with a thick blue horizontal bar at the top. A vertical blue line runs down the right side, and another vertical line runs down the left side, intersecting a horizontal blue line that spans the width of the slide. At the intersection of the left vertical line and the horizontal line, there is a small blue circle. At the intersection of the right vertical line and the horizontal line, there is a small blue circle. The text "Software Testing" is centered in a large, bold, purple font.

Software Testing

Overview

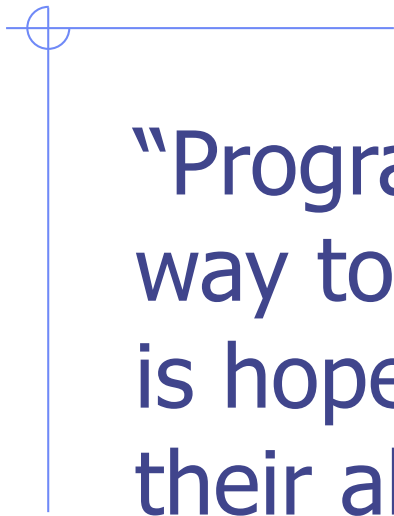

- ◆ Definition of Software Testing
- ◆ Problems with Testing
- ◆ Benefits of Testing
- ◆ Effective Methods for Testing

Definition of Software Testing

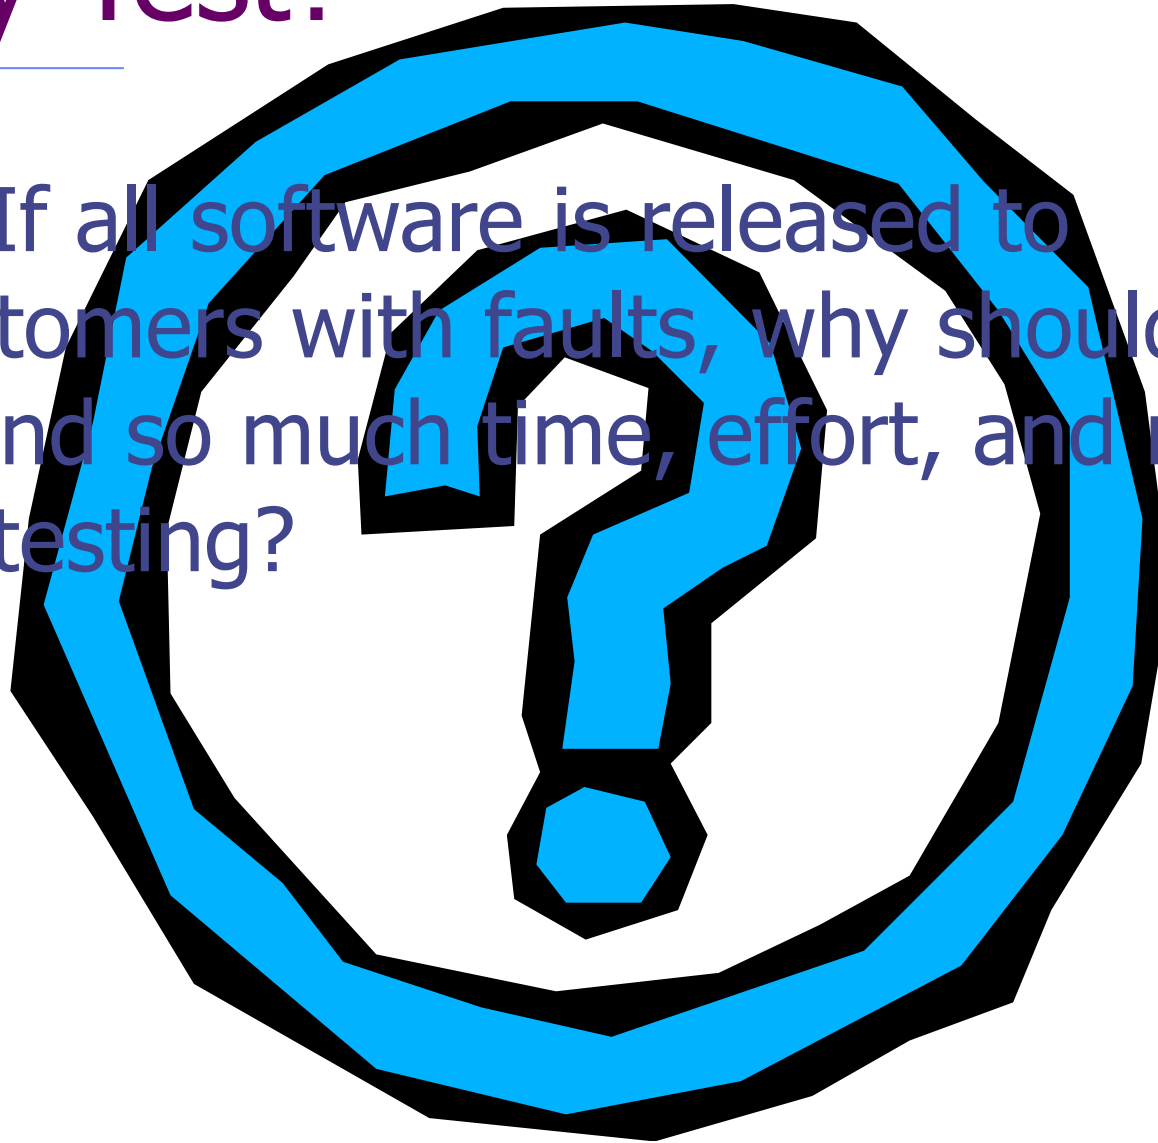

Software testing is the process of executing a software system to determine whether it matches its specification and executes in its intended environment.

“Program testing can be a very effective way to show the presence of bugs, but it is hopelessly inadequate for showing their absence” [Dijkstra, 1972]

Why Test?

Q: If all software is released to customers with faults, why should we spend so much time, effort, and money on testing?

Cost of Delaying the Release of a Software Product

- ◆ Timing is another important factor to consider.
- ◆ New products: The first to the market often sells better than superior products that are released later.

Beta Testing

- ◆ Customers test for free!
- ◆ Seems to give you test cases representative of customer use.
- ◆ Helps to determine what is most important to the customers.
- ◆ Can do more configuration (environment) testing than in your testing lab.

Problems with Beta Testing

- ◆ Most beta testers are “techies” who have a higher tolerance of bugs. They do not represent the average customer.
- ◆ Beta testers usually won't report: usability problems, bugs they don't understand and bugs that seem obvious.
- ◆ Takes much more time and effort to handle a user reported bug.

Cutting Testing Costs can Increase other Costs

- ◆ Customer support can be very expensive. Less bugs = less calls.
- ◆ Customers will look for more reliable solutions.
- ◆ Software organizations must perform cost benefit analysis' to determine how much to spend on testing.

Problems with Testing

Since it is impossible to find every fault in a software system, bugs will be found by customers after the product is released.

Another Problem

In many software companies, testers are ill-equipped to test software. For example: My last co-op firm (which will remain unnamed).

- ◆ Testing done almost entirely by untrained co-ops.
- ◆ Testers were responsible for creating black-box test plans without being given formal specifications.
- ◆ Testers were not provided with tools to automate test plans.

Reasons that Bugs Escape Testing

- ◆ User executed untested code.
- ◆ User executed statements in a different order than was tested.
- ◆ User entered an untested combination of inputs.
- ◆ User's operating environment was not tested.

Why Can't Every Bug be Found?

- ◆ Too many possible paths.
- ◆ Too many possible inputs.
- ◆ Too many possible user environments.

Too Many Possible Paths

Too Many Possible Inputs

- ◆ Programs take input in a variety of ways: mouse, keyboard, and other devices.
- ◆ Must test Valid and Invalid inputs.
- ◆ Most importantly, there are an infinite amount of sequences of inputs to be tested.

Too Many Possible User Environments

- ◆ Difficult to replicate the user's combination of hardware, peripherals, OS, and applications.
- ◆ Impossible to replicate a thousand-node network to test networking software.

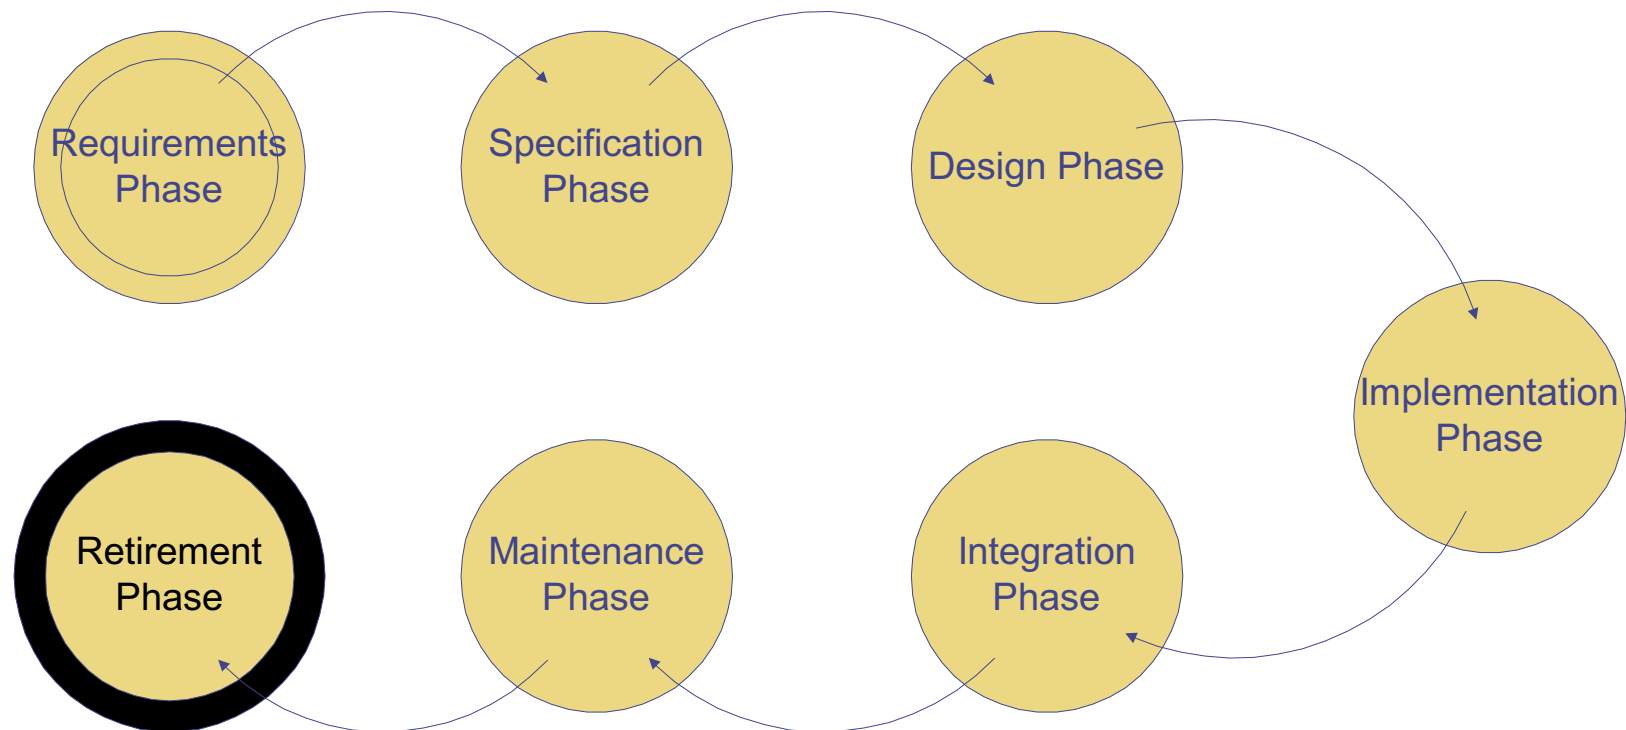

How is Testing Done

Phases of the Software Process

Why No Testing Phase?

- ◆ Testing must be done at every phase.
- ◆ Testing of a phase must be build upon and checked against the results of the previous phase.
- ◆ Non-execution based testing is done in early phases (before executable code is produced).
- ◆ Execution and non-execution based testing can be done in later phases.

Nonexecution-Based Testing

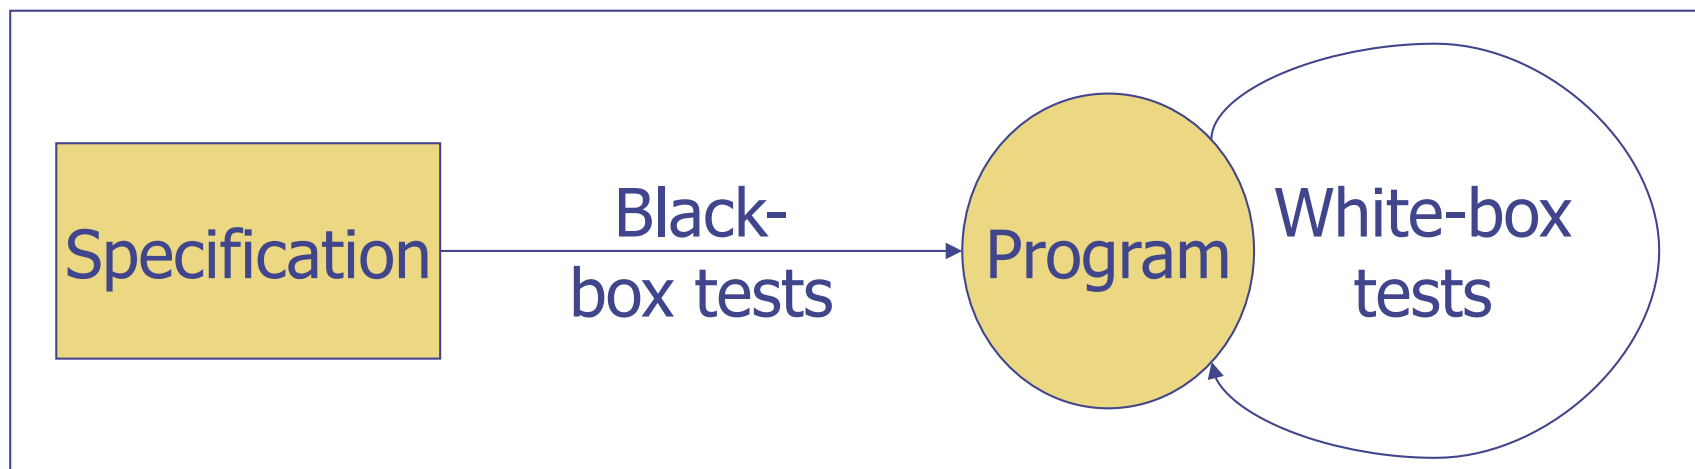

- ◆ Walkthroughs
- ◆ Inspections
- ◆ Walkthroughs are shorter and more informal than inspections.
- ◆ Goal of both is to record faults, not to correct them.

Execution-Based Testing

- ◆ Utility
- ◆ Reliability
- ◆ Robustness
- ◆ Performance
- ◆ Correctness

Black-Box / White-Box Testing

- ◆ Black-box tests are driven by the program's specification
- ◆ White-box tests are driven by the program's implementation

Test Automation

- ◆ If a manual test costs \$X to run the first time, it will cost \$X to run every time thereafter.
- ◆ An automated test can cost 3 to 30 times \$X the first time, but will cost about \$0 after that.

Any Questions?

Too Many Possible Paths

- ◆ There are 5 paths from A to X without passing through the loop.
- ◆ There are 5^{20} paths from A to X after passing through the loop 20 times.
- ◆ There are $5 + 5^2 + 5^3 + \dots + 5^{20} = 100$ trillion possible paths in this program.
- ◆ If you could test a path per second it would take more than 3 million years!

Black Box Testing

- ◆ Checks that the product conforms to specifications
- ◆ Cannot determine how much code has been tested

White Box Testing

- ◆ Allows tester to be sure every statement has been tested.
- ◆ Difficult to discover missing functionality.
